

11-1 INTRODUCTION

In this chapter, the effect of the project's operation on air quality is analyzed and includes a description of the regulatory context, methods of analysis, existing air quality, and the future air quality with the project. Air quality effects during construction are analyzed in Chapter 18, "Construction Impacts".

Since the project would not increase overall traffic volumes (see Chapter 4, "Transportation"), the analysis focuses on changes in roadway and bridge configuration which may affect air quality at nearby residential locations and other land uses. Regional (i.e., mesoscale) emissions would not change due to the project, and the project would not introduce any new permanent stationary sources.

11-2 REGULATORY CONTEXT

11-2-1 POLLUTANTS FOR ANALYSIS

Emissions from motor vehicles result from combustion of fuels—predominantly gasoline and diesel.

Carbon monoxide (CO), particulate matter (PM), volatile organic compounds (VOCs), and nitrogen oxides (nitric oxide, NO, and nitrogen dioxide, NO₂, collectively referred to as NO_x) are all emitted from the combustion of both gasoline and diesel. CO emissions are predominantly from gasoline combustion. While NO_x and PM emissions are mostly from diesel combustion, substantial amounts are also emitted from gasoline vehicles.¹ Fine PM is also formed when emissions of NO_x, sulfur oxides (SO_x, which includes SO₂ and other sulfur oxides), ammonia, organic compounds, and other gases react or condense in the atmosphere. Ozone is formed in the atmosphere by complex photochemical processes that include NO_x and VOCs.

For microscale on-road emissions, the pollutants of concern include CO and PM, and both are included in this analysis for the project. Overall, the efforts to reduce CO emissions from motor vehicles due to federal regulations over the past few decades have been very successful, and CO concentrations are generally not of concern in New York State, although regulations are maintained to ensure continued compliance. VOC emissions are mainly of concern as ozone precursors on a mesoscale (regionwide), and are, therefore, not addressed here for the microscale analysis of the project.

¹ Light-duty vehicles, which are predominantly gasoline powered, emit these pollutants at a much lower rate than heavy diesel trucks, but due to the larger number of light gasoline vehicles, the total amount from light-duty vehicles is substantial.

Tappan Zee Hudson River Crossing Project Environmental Impact Statement

As described below, PM is regulated in two size categories: particles with an aerodynamic diameter of less than or equal to 2.5 micrometers (PM_{2.5}), and particles with an aerodynamic diameter of less than or equal to 10 micrometers (PM₁₀, which includes PM_{2.5}). PM_{2.5} has the ability to reach the lower regions of the respiratory tract, delivering with it other compounds that adsorb to the surfaces of the particles, and is also extremely persistent in the atmosphere. PM_{2.5} is mainly derived from combustion material that has volatilized and then condensed to form primary PM (often soon after the release from a source exhaust) or from precursor gases reacting in the atmosphere to form secondary PM. Diesel-powered engines are a substantial source of respirable PM, most of which is PM_{2.5}.

In addition to being a precursor to the formation of ozone, NO₂ (one component of NO_x) is also a regulated pollutant. Since NO₂ is mostly formed from the transformation of NO in the atmosphere, it has mostly been of concern further downwind from large stationary point sources, and not a local concern from mobile sources. (NO_x emissions from fuel combustion consist of approximately 90 percent NO and 10 percent NO₂ at the source.) However, with the promulgation of the 2010 1-hour average standard for NO₂, local sources such as vehicular emissions may become of greater concern for this pollutant, and, therefore, NO₂ from the project is discussed as well.

Emissions of sulfur dioxide (SO₂) are currently associated mainly with stationary sources and with some sources utilizing non-road diesel such as diesel trains and marine engines. On-road diesel vehicles currently contribute very little to SO₂ emissions since the sulfur content of on-road diesel fuel, which is federally regulated, is extremely low. Similarly, non-road diesel federal regulations are being phased in by 2012 (with minor exceptions as late as 2015, not affecting this project) requiring the phase out of sulfur in diesel for all uses. Therefore, SO₂ is not currently of concern for on-road emissions, and will not be an issue of concern beginning in the near future from transportation sources in general. Similarly, lead in gasoline has been banned under the Clean Air Act (CAA) and is, therefore, not a pollutant of concern for the project. Therefore, SO₂ and lead have not been included in this analysis.

In addition to the criteria pollutants discussed above, non-criteria pollutants may be of concern. These pollutants are sometimes referred to as hazardous pollutants or as Mobile Source Air Toxics (MSATs) in the on-road context. Some MSATs such as benzene and toluene from vehicles are controlled by fuel and tailpipe emissions regulations. Although MSATs are not generally of concern on an areawide basis, transportation projects sometimes report area-wide (mesoscale) emissions. The project would not increase overall traffic volumes (see Chapter 4, "Transportation"), and therefore overall MSAT emissions would not change.

11-2-2 NATIONAL AND STATE AIR QUALITY STANDARDS

As required by the CAA, primary and secondary National Ambient Air Quality Standards (NAAQS) have been established for six major air pollutants: CO, NO₂, ozone, respirable PM (both PM_{2.5} and PM₁₀), SO₂, and lead. The primary standards represent levels that are designed to protect the public health, allowing an adequate margin of safety. The secondary standards are intended to protect the nation's welfare, and account for air pollutant effects on soil, water, visibility, materials, vegetation, and other aspects of the

environment. The NAAQS are presented in **Table 11-1**. The NAAQS for CO, annual NO₂, and SO₂ have also been adopted as the ambient air quality standards for New York State, but are defined on a running 12-month basis rather than for calendar years only.

Table 11-1
National Ambient Air Quality Standards (NAAQS)

Pollutant	Primary		Secondary	
	ppm	µg/m ³	ppm	µg/m ³
<i>Carbon Monoxide (CO)</i>

11-2-3 NAAQS ATTAINMENT STATUS AND STATE IMPLEMENTATION PLANS

The CAA, as amended in 1990, defines non-attainment areas (NAA) as geographic regions that have been designated as not meeting one or more of the NAAQS. When an area is designated as non-attainment by the United States Environmental Protection Agency (USEPA), the state is required to develop and implement a State Implementation Plan (SIP), which delineates how a state plans to achieve air quality that meets the NAAQS under the deadlines established by the CAA, followed by a plan for maintaining attainment status once the area is in attainment. SIPs normally include emissions budgets for all sources (motor vehicle, nonroad, point sources, and area sources) that the NAA is expected to meet. The NAAs containing the project study area or part of the study area are presented in **Table 11-2**.

Table 11-2
Non-Attainment Areas in the Project Study Area

Pollutant	NAA Name	Severity	Counties
Ozone	New York-N. New Jersey-Long Island, NY-NJ-CT	Moderate (designated severe for the 1-hour ozone standard)	Bronx Kings Nassau New York Queens Richmond Rockland Suffolk Westchester
CO	New York-N. New Jersey-Long Island, NY-NJ-CT	Maintenance (moderate)	Bronx Kings Nassau New York Queens Richmond Westchester
PM _{2.5}	New York-N. New Jersey-Long Island, NY-NJ-CT	Non-attainment	Bronx Kings Nassau New York Queens Richmond Rockland Suffolk Westchester Orange
Sources: EPA, Greenbook, http://www.epa.gov/oar/oaqps/greenbk/ , accessed 2010.			

Effective June 15, 2004, USEPA designated New York City and Nassau, Rockland, Suffolk, and Westchester counties as a moderate NAA for the 1997 8-hour average ozone standard (the NY portion of the New York–Northern New Jersey–Long Island, NY-NJ-CT NAA). In 2008, the New York State Department of Environmental Conservation (NYSDEC) submitted a proposed motor vehicle emissions budget (MVEB) for this NAA for public review and comment, and effective August 17, 2010, USEPA determined that said proposed MVEB was adequate for use in transportation

conformity analyses. It is this MVEB to which the New York Metropolitan Transportation Council's (NYMTC) Transportation Improvement Program (TIP) and Regional Transportation Plan (Plan) have to conform.

In March 2008 USEPA strengthened the 8-hour ozone standards. SIPs for the new 8-hour ozone standard will be due three years after the final designations are made. On March 12, 2009, NYSDEC recommended that the counties of Suffolk, Nassau, Bronx, Kings, New York, Queens, Richmond, Rockland, and Westchester be designated as an NAA for the 2008 ozone NAAQS (NY portion of the New York-Northern New Jersey-Long Island, NY-NJ-CT NAA). EPA has agreed, under consent decree, to promulgate area designations for the 2008 ground-level ozone NAAQS no later than May 31, 2012.

New York County is the only county in the region designated as an NAA for PM₁₀ (moderate). The five New York City counties and Nassau, Suffolk, Rockland, Westchester, and Orange Counties is designated as a PM_{2.5} NAA (the New York-Northern New Jersey-Long Island, NY-NJ-CT NAA) due to exceedance of the 1997 annual average standard. Based on recent monitoring data (2006-2009), annual average concentrations of PM_{2.5} in this area no longer exceed the annual standard. USEPA has determined that the area has attained the 1997 annual PM_{2.5} NAAQS, effective December 15, 2010.

The New York Metropolitan Area (NYMA) is designated as nonattainment with the 2006 24-hour PM_{2.5} NAAQS. The NAA includes the same 10-county area originally designated as nonattainment with the 1997 annual PM_{2.5} NAAQS. Based on recent monitoring data (2007-2009), 24-hour average concentrations of PM_{2.5} in this area no longer exceed the annual standard. New York has submitted a "Clean Data" request to the USEPA. Any requirement to submit a SIP is stayed until EPA acts on New York's request.

Annual average NO₂ concentrations monitored at existing NO₂ monitoring stations to-date have all been lower than the NAAQS. As described above, USEPA has recently promulgated a new 1-hour NO₂ standard. The existing monitoring data indicates background concentrations below the standard at all existing New York State monitoring stations. However, NYSDEC has determined that the present monitoring does not meet the revised USEPA requirements in all respects and has recommended a designation of "unclassifiable" for the entire state. Therefore, it is likely that the NYMA will be designated by USEPA as "unclassifiable" at first (January 2012), and then designated with a final classification once three years of monitoring data are available (2016 or 2017).

Based on the available monitoring data, all areas in New York State currently meet the new 1-hour SO₂ standard. Additional monitoring and refined modeling of large sources may be required. USEPA plans to make final attainment designations in June 2012, based on 2008 to 2010 monitoring data and refined modeling. SIPs for NAAs will be due by June 2014.

In 2002, USEPA re-designated the New York City area, including Westchester County, as in attainment for CO. Under the resulting maintenance plan, New York City is committed to implementing site-specific control measures throughout the city to reduce CO levels, should unanticipated localized growth result in elevated CO levels during the maintenance period. There are no site-specific control measures in Westchester

Tappan Zee Hudson River Crossing Project Environmental Impact Statement

County. The approved maintenance plan also includes an MVEB for CO to which the seven-county area must conform.

11-2-4 CONFORMITY WITH STATE IMPLEMENTATION PLANS

The conformity requirements of the CAA and regulations promulgated thereunder (conformity requirements) limit the ability of federal agencies to assist, fund, permit, and approve projects in non-attainment or maintenance areas that do not conform to the applicable SIP. When subject to this regulation, the lead federal agency is responsible for demonstrating conformity of its proposed action. Conformity determinations for federal actions related to transportation plans, programs, and projects which are implemented, funded, or approved under title 23 U.S.C. or the Federal Transit Act (49 U.S.C. 1601 et seq.) must be made by the project's lead federal transportation agency—in the case of this project, FHWA—according to the requirements of 40 CFR §93, Subpart A (federal transportation conformity regulations).

The following criteria and procedures apply for projects from a currently conforming TIP and regional transportation plan:

- The project must not cause or contribute to any new localized CO, PM₁₀, and/or PM_{2.5} violations, increase the frequency or severity of any existing CO, PM₁₀, and/or PM_{2.5} violations, or delay timely attainment of any NAAQS or any required interim emission reductions or other milestones in CO, PM₁₀, and PM_{2.5} nonattainment and maintenance areas.
- The project must comply with any PM₁₀ and PM_{2.5} control measures in the applicable implementation plan. This criterion is satisfied if the project-level conformity determination contains a written commitment from the project sponsor to include in the final plans, specifications, and estimates for the project those control measures (for the purpose of limiting PM₁₀ and PM_{2.5} emissions from the construction activities and/or normal use and operation associated with the project) that are contained in the applicable implementation plan.

The Interagency Consultation Group (ICG) in New York State includes representatives from the FHWA, USEPA, NYSDEC, New York State Department of Transportation (NYSDOT), and the Metropolitan Planning Organizations. The ICG provides multi-agency concurrence on the assumptions and methodologies used in the travel demand models, the results of which form the basis of the regional emissions analysis in the TIPs and Plans. The modeling inputs and parameters used in the analyses for the current NYMTC 2011-2015 TIP and 2035 Plan were established in consultation with the NYSDEC and the New York State ICG.

The ICG determined that the 8-lane Replacement Bridge Alternative is a non-exempt project under the air quality conformity regulations and thus must be included in the regional transportation emissions analyses. The existing analyses of NYMTC's current conforming Plan and TIP includes the existing operational configuration of a 7-lane facility with a movable barrier that provides four lanes in the peak direction. The 8-lane alternative without a movable barrier would be operationally very similar. The 8-lane alternative will be included in the emission analyses for the amended 2011-2015 TIP and 2035 Plan in July, before the Record of Decision for the project is published.

Regarding the transportation conformity process for quantitative hot-spot analyses, the ICG reviewed and accepted the models, methods and assumptions used in this environmental document.

As described in Chapter 4, "Transportation," the project is not expected to affect a net change in vehicle miles traveled and the ensuing on-road emissions during the operation of the project as compared to the future condition included in the currently conforming TIP and plan. According to the conformity regulations (40 CFR §93.116), the project will not cause or contribute to any new local CO, PM₁₀, and/or PM_{2.5} violations, increase the frequency or severity of any existing violations, or delay timely attainment of any NAAQS, emissions reductions, or other milestones, if the project is not identified in the following criteria (40 CFR §93.123):

- For projects in or affecting locations, areas, or categories of sites which are identified in the applicable implementation plan as sites of violation or possible violation;
- For projects affecting intersections that are at Level-of-Service D, E, or F, or those that will change to Level-of-Service D, E, or F because of increased traffic volumes related to the project (for PM, this applies only to intersections with a large number of diesel vehicles);
- For any project affecting one or more of the top three intersections in the nonattainment or maintenance area with highest traffic volumes or the top three intersections in the nonattainment or maintenance area the worst level of service, as identified in the SIP.

In addition, for PM only, procedures for hotspot analysis are required to be used—

- For new highway projects that have a substantial number of diesel vehicles, and expanded highway projects that have a substantial increase in the number of diesel vehicles;
- New bus and rail terminals and transfer points that have a substantial number of diesel vehicles congregating at a single location; and
- Expanded bus and rail terminals and transfer points that substantially increase the number of diesel vehicles congregating at a single location.

In cases other than those described above, the demonstrations required may be based on qualitative consideration of local factors, if this can provide a clear demonstration that the above requirements (40 CFR §93.116) are met. Since the project is not a new highway, will not affect traffic volume or vehicle classification, will not affect any intersections, and will not introduce any bus or rail components, hotspot analyses are not required for conformity purposes.

Nonetheless, analyses of the effect of the change in roadway alignment on concentrations nearby were prepared to meet the requirements of the National Environmental Policy Act (NEPA) and New York State Environmental Quality Review Act (SEQRA). The analyses presented below demonstrate that the project would not cause or contribute to any new localized CO, PM₁₀, or PM_{2.5} violations.

11-3 METHODOLOGY

Since the project would not increase traffic volumes and would not reduce levels of service (see Chapter 4, “Transportation”), the mobile source assessment is focused on potential air quality effects of CO and PM emissions that could result from the project roadway reconfiguration. The assessment follows the procedures outlined in NYSDOT’s *The Environmental Manual (TEM)*, January 2001, and NYSDOT’s *Project Level Particulate Matter Analysis Policy*, September 2004.

11-3-1 SCREENING ANALYSIS

According to the NYSDOT *TEM* ‘capture criteria,’ CO microscale analysis is required if the Build condition level of service is at D, E, or F and the project would result in a 10 percent or more reduction in the distance between source and receptor (locations where potential air quality is analyzed, such as residential or open space locations), and if traffic volume screening thresholds would be exceeded. The slight shift in the replacement bridge’s location would require an adjustment in the roadway on the bridge landing sites and connection to the existing roadway, resulting in the nearest lane being closer by more than 10 percent to some adjacent residential locations (and further from receptors on the opposite side), and the free flow traffic volumes on the bridge would exceed the volume screening threshold. Therefore, a detailed CO analysis was conducted in the area of both bridge landings (on the Rockland and Westchester sides).

The NYSDOT policy, like the conformity hotspot guidance described above, does not require analysis for projects that would not result in increased traffic volumes, unless other factors have potential to result in increased PM emissions, but does not otherwise provide any screening procedures. Although the project would not increase emissions, and therefore PM analysis is not strictly required according to the NYSDOT policy, the project would shift the roadway source closer to some receptor locations, as described above for CO. Therefore, detailed PM analyses were prepared for the same locations described above for CO.

11-3-2 ROADWAY EMISSIONS AND DISPERSION ANALYSIS

The prediction of vehicle-generated emissions and their dispersion incorporates meteorological phenomena, traffic conditions, and physical configurations. Air pollutant dispersion models mathematically simulate the combined effect of traffic, meteorology, and geometry on pollutant concentrations. The mathematical expressions and formulations contained in the various models attempt to describe an extremely complex physical phenomenon as closely as possible. However, because all models contain simplifications and approximations of actual conditions and interactions, and because it is necessary to predict the reasonable worst-case condition, most of these dispersion models predict conservatively high pollutant concentrations, particularly under adverse meteorological conditions. The mobile source analysis for the project employs a modeling approach approved by USEPA. The modeling approach includes a series of conservative assumptions relating to meteorology, traffic, and background concentration levels which result in a conservatively high estimate of expected concentrations.

11-3-2-1 VEHICLE EMISSIONS

Vehicular exhaust emission factors, which were computed by NYSDOT using the USEPA Mobile Source Emissions Model, MOBILE6.2,¹ and presented in NYSDOT's *TEM*, were used for the CO and PM dispersion analyses. The database includes emission factors by county, vehicle class, roadway functional class, and speed. MOBILE6.2 is capable of calculating engine emission factors for various vehicle types, based on the fuel type (gasoline, diesel, or natural gas), meteorological conditions, vehicle speeds, vehicle age, roadway types, number of starts per day, engine soak time, and various other factors that influence emissions, such as inspection maintenance programs.

TEM provides emission factors up to year 2035. Through the consultation with the NYSDOT Office of Environment, the analysis used year 2035 emission factors for later years, conservatively combining higher emission factors with higher traffic volumes (see more below regarding analysis years).

In addition to exhaust emissions, the PM₁₀ analyses include resuspended road dust. Resuspended paved-road dust emission rates were calculated using the procedures published by USEPA (USEPA, AP-42, January 2011). According to USEPA's guidance² and in agreement with NYSDOT, PM_{2.5} fugitive dust is considered negligible and does not need to be included in mobile source microscale modeling analysis. Therefore, PM_{2.5} emissions include only engine exhaust, brake wear, and tire wear (from *TEM*).

11-3-2-2 ANALYSIS YEARS

According to the *TEM*, CO and PM impact analyses are required for the Estimated Time of Completion (ETC) and the year with highest corridor emission levels of ETC+10, ETC+20, and, for major bridge projects, ETC+30. The ETC for the project is 2017.

In order to determine the year with the highest corridor emissions, emissions associated with the forecasted traffic volumes for each year were calculated. This calculation, presented in **Table 11-3**, incorporates the projected increase in traffic volume in future years and the decrease in vehicular emissions associated with improved vehicle technology in future years (total emissions = average emission factor x traffic volume.)

The NYSDOT-published emission factors (available up to the year of 2035) generally decrease in earlier years, but level off starting in approximately 2027 or soon thereafter. Traffic volumes in the study area are projected to increase by about 0.3 percent and 0.2 percent per year in the AM and PM periods, respectively.

**Table 11-3
Net Emission Rate Calculation by Analysis Year**

	2017	2027	2037	2047
AM Peak Hour				
Total Bridge Traffic Volume	11,783	12,133	12,863	12,863
CO Factor (g/veh-mile at 55 mph)	3.6	3.3	3.3	3.3
<i>CO Rate (g/mile at 55 mph)</i>	42,834	<i>40,516</i>	<i>42,960</i>	42,960
PM _{2.5} Factor (g/veh-mile at 55 mph)	0.014	0.012	0.012	0.012
<i>PM_{2.5} Rate (g/mile at 55 mph)</i>	169	<i>152</i>	<i>155</i>	155
PM Peak Hour				
Total Bridge Traffic Volume	11,678	11,916	12,408	12,408
CO Factor (g/veh-mile at 55 mph)	3.6	3.3	3.3	3.3
<i>CO Rate (g/mile at 55 mph)</i>	42,452	<i>39,795</i>	<i>41,440</i>	41,440
PM _{2.5} Factor (g/veh-mile at 55 mph)	0.014	0.012	0.012	0.012
<i>PM_{2.5} Rate (g/mile at 55 mph)</i>	168	<i>149</i>	<i>149</i>	149
Notes:	Idle emissions or lower speeds at the toll plaza would result in similar conclusions.			
Sources:	Traffic volumes from Paramix model (see Chapter 14, "Transportation") Emission Rates from NYSDOT's TEM			

The projected emission factors will generally decrease more than the projected increase in traffic volumes in early years, and then level off in future years while traffic volumes continue to grow. Overall, emissions would be highest in 2017. In 2027 emissions would be lower than in 2017 due to ongoing improvements in vehicle technology in earlier years, and then begin to increase as traffic volumes grow. Therefore, detailed air quality analyses were conducted for ETC (2017) and ETC+30 (2047).

11-3-2-3 DISPERSION MODEL FOR MICROSCALE ANALYSES

Maximum CO and PM concentrations resulting from vehicle emissions at the bridge landing site in Rockland County were predicted using USEPA's CAL3QHC model version 2.0.¹ The CAL3QHC model employs a Gaussian (normal distribution) dispersion assumption and includes an algorithm for estimating vehicular queue lengths at signalized intersections. CAL3QHC is used to conservatively predict the dispersion from idling and moving vehicles based on peak traffic and meteorological conditions.

A different modeling approach was used to analyze impacts around the bridge landing area in Westchester County, including the bridge's toll plaza. The toll plaza operates as a series of many line sources including queues, and is, therefore, better represented as an area source. Area sources are better simulated by the USEPA-approved model AERMOD. AERMOD is a steady-state plume dispersion model and simulates dispersion from multiple point, area, or volume sources. Dispersion characteristics may be selected to model rural or urban conditions, and terrain effects can be modeled to

¹ USEPA, User's guide to CAL3QHC—A Modeling Methodology for Predicting Pollutant Concentrations Near Roadway Intersections, Office of Air Quality Planning and Standards, Research Triangle Park, North Carolina, September 1995.

reflect simple or complex terrain. The model employs hourly sequential preprocessed meteorological data to estimate concentrations for selected averaging times from one hour to one year.

11-3-2-4 METEOROLOGY

In general, the transport and concentration of pollutants from vehicular sources are influenced by three principal meteorological factors: wind direction, wind speed, and atmospheric stability. Wind direction influences the direction in which pollutants are dispersed from a given source, and wind speed and atmospheric stability affect the extent of mixing in the atmosphere.

Following the *TEM* and USEPA guidelines¹, CAL3QHC computations were performed using a wind speed of 1 meter per second, and the neutral stability class, D (for urban environments). The wind angle was varied to determine the maximum concentrations at each receptor under all wind conditions, regardless of frequency of occurrence. 8-hour average CO concentrations were estimated by multiplying the predicted 1-hour average CO concentrations by a factor of 0.70 to account for persistence of meteorological conditions; similarly, a 24-hour persistence factor of 0.4 and an annual persistence factor of 0.08 were used to obtain 24-hour and annual average PM concentrations. A surface roughness of 1.08 meters was chosen. These assumptions ensured that worst-case meteorology was used to estimate impacts.

The latest available five years of hourly meteorological data were employed in the AERMOD model: surface data collected at LaGuardia Airport and concurrent upper air data collected at Brookhaven, Suffolk County, New York from 2005 through 2009. All hours were modeled, and the highest resulting concentration for each averaging period is presented.

11-3-2-5 TRAFFIC DATA

Traffic data for the air quality analysis were modeled based on existing traffic counts, projected future growth in traffic, and other information developed as part of the traffic analysis for the project (see Chapter 4, "Transportation"). Traffic data for the future with and without the project were employed in the respective air quality modeling scenarios. Peak hour periods were used for microscale CO and PM analysis around the bridge landing site in Rockland County (using CAL3QHC), producing the maximum anticipated project-generated traffic and the greatest potential for air pollutant emissions. This assumption results in conservatively high concentrations since the peak hour traffic is used for all hours. The modeling of bridge traffic at the landing area in Westchester County (using AERMOD) applied hourly traffic distribution.

11-3-2-6 BACKGROUND CONCENTRATIONS

Background concentrations are pollutant concentrations originating from distant sources that are not directly included in the modeling analysis, which directly accounts for vehicular emissions within 1,000 feet and in the line of sight of the analysis site.

¹ USEPA, *Guidelines for Modeling Carbon Monoxide from Roadway Intersections*, USEPA Office of Air Quality Planning and Standards, EPA-454/R-92-005, 1992.

Tappan Zee Hudson River Crossing Project Environmental Impact Statement

Background concentrations are added to modeling results to obtain total pollutant concentrations at an analysis site.

Background concentrations were conservatively assumed to be the same as those monitored in the existing condition, presented in Section 11-4, "AFFECTED ENVIRONMENT," Background concentrations of PM and CO have been declining over the years and are expected to continue to decrease, as demonstrated by many monitored concentrations in the region.

PM analyses do not generally include background concentrations since the projected increases in concentration are compared with NYSDOT's incremental thresholds.

11-3-2-7 RECEPTOR LOCATIONS

Concentrations were modeled at multiple receptors at both analysis sites. The receptors were placed at spaced intervals along sidewalk or roadside locations with continuous public access, and at residential locations. The receptors placed on sidewalks were located at least 3 meters from each of the traveled roadways. Concentrations were calculated at receptors placed at 25-meter intervals along the sidewalk. Ground-level receptors were placed at a height of 1.8 meters, and elevated residential windows were included as well. Receptor locations in the Rockland County and Westchester County models are presented in **Figures 11-1 and 11-2**, respectively.

11-3-3 EVALUATING AIR QUALITY IMPACTS

The relative importance of a predicted consequence of a project (i.e., whether it is material, substantial, large or important) should be assessed in connection with its context and setting (e.g., urban or rural), and its intensity (including probability of occurrence, duration, irreversibility, geographic scope, magnitude, and number of people affected). For the purposes of this evaluation, the term 'adverse impact' is used to indicate an impact of importance based on the above criteria, and not simply any increase in pollutant concentrations.

In terms of the magnitude of air quality impacts, any action predicted to increase the concentration of a criteria air pollutant to a level that would exceed the NAAQS concentrations (see **Table 11-1**) would be deemed to have a severe potential adverse impact. In addition, in order to maintain concentrations lower than the NAAQS in attainment areas, or to ensure that concentrations will not be substantially increased in NAAs, threshold levels have been defined for certain pollutants; any action predicted to increase the concentrations of these pollutants above the thresholds could be deemed to have a potential adverse impact, even in cases where violations of the NAAQS are not predicted, depending on the context, intensity, and frequency of the exceedance.

NYSDOT requires that operational PM impacts be estimated for all of their projects that exceed listed thresholds in the final interim policy (September 2004), regardless of project location or attainment status. Maximum PM₁₀ and PM_{2.5} incremental concentrations or emission differences found to be greater than those thresholds, listed below, will be determined to represent a potential adverse environmental impact.

PM₁₀ Potential Adverse Impact Thresholds—

Microscale Analysis:

- Greater than 5.0 µg/m³ on a 24-hour basis.

Mesoscale Analysis:

- Greater than two percent increase in emission burden.

PM_{2.5} Potential Adverse Impact Thresholds—

Microscale Analysis:

- Greater than two percent of NAAQS annual Standard or 0.3 µg/m³, or
- Greater than 5.0 µg/m³ on a 24-hour basis.

Mesoscale Analysis:

- Greater than two percent increase in emission burden.

11-4 AFFECTED ENVIRONMENT

The NYSDEC ambient air quality monitoring network was established to monitor potential statewide air quality. For areas without monitoring stations, air quality can be characterized as similar to that measured at the nearest stations that are similar in land use and air pollution sources to the area under study. The most recent concentrations of relevant criteria pollutants (2008–2010) measured at ambient air quality monitoring stations nearest to the project are presented in **Table 11-4**. The ambient air concentrations measured at all listed stations were below the corresponding NAAQS, except for exceedances of the 8-hour ozone standard recorded in both Orange and Westchester Counties within the 3-year period. The CO and PM concentrations were also applied as background levels in the microscale analysis.

11-5 ENVIRONMENTAL EFFECTS

11-5-1 NO BUILD ALTERNATIVE

In the No Build Alternative, air quality in the general area of the project would be similar to the existing condition described above, with some improvements in air quality expected to occur over the years resulting from statewide efforts to reduce pollution and improved vehicular technology as older vehicles are replaced with newer, cleaner engines. However, in the immediate vicinity of the existing bridge, concentrations higher than these background conditions would be expected (as is the case in the existing condition) due to the large volumes of traffic using the bridge, bridge approaches, and toll plaza. Future No Build concentrations were projected in the microscale model, and are presented along with the Replacement Bridge Alternative results in the following section (Table 11-4).

Furthermore, under the No Build Alternative, heavy congestion and delays resulting from accidents and vehicle breakdowns on the bridge, where no shoulders or emergency lanes are available to clear the roadway, would persist, resulting in avoidable emissions. Additionally, maintenance operations would be more intense under the No Build Alternative than under the Replacement Bridge Alternative, resulting in some additional emissions.

**Table 11-4
Representative Monitored Ambient Air Quality Data for Criteria
Pollutants, 2008 to 2010**

Pollutant and Averaging Time	Monitored Data				NAAQS	Monitoring Site Location
	2008	2009	2010	3-year Average		
<i>Carbon Monoxide</i> (ppm)						
8-hour	1.8	2.5	1.6	NR	9	New York City (Bronx) 200th Street and Southern Boulevard
1-hour	2.3	3.4	2.1	NR	35	
<i>Ozone</i> (ppm)						
8-hour 4 th -highest Daily Maximum	0.082	0.075	0.075	0.077	0.075	Westchester (White Plains) Pump Station Orchard Street
<i>Ozone</i> (ppm)						
8-hour 4 th -highest Daily Maximum	0.080	0.066	0.075	0.074	0.075	Orange (Montgomery) 1175 Route 17K
<i>Nitrogen Dioxide</i> (ppm)						
Annual Arithmetic Mean	0.024	0.023	0.022	0.023	0.050	New York City (Bronx) Botanical Gardens
<i>PM₁₀</i> (µg/m ³)						
24-Hour Maximum	60	64	no data	NR	150	New York City (Bronx) IS52
<i>PM_{2.5}</i> (µg/m ³)						
Annual Arithmetic Mean	11.0	9.1	8.8	9.6	15	Westchester (Mamaroneck) 5th Avenue and Madison
24-Hour 98 th Percentile	30.4	27.0	26.7	28	35	
<i>PM_{2.5}</i> (µg/m ³)						
Annual Arithmetic Mean	9.5	7.9	8.2	8.5	15	Orange (Newburgh) 55 Broadway
24-Hour 98 th Percentile	26.0	20.6	26.5	24	35	

Note: NR—not relevant

11-5-2 REPLACEMENT BRIDGE ALTERNATIVE

The air quality resulting from the Long Span and Short Span Options for the Replacement Bridge Alternative would be essentially the same; the slight differences in predicted concentrations, presented below, result from somewhat different elevations and roadway configuration at the bridge landing sites. The traffic would be the same, and the bridge alignment and receptor locations would be largely the same.

The results of the CO microscale modeling including background levels are presented in **Table 11-5** and are compared with the NAAQS for CO. The highest CO concentrations under the build conditions were predicted to occur along the new shared-use path since it would be the location closest to Interstate 87/287 traffic along the bridge and toll plaza. However, the predicted microscale CO levels would all be below the 1-hour CO NAAQS of 35 ppm or 8-hour CO NAAQS of 9 ppm. Consequently, the Replacement Bridge Alternative would not result in an adverse microscale CO air quality impact. (Note that the shared-use path would be located on the north side of the north span of the bridge, and would be separated from the nearest moving lane by 12-feet (shoulder and safety barrier).)

Table 11-5
Total Maximum Predicted CO Concentrations (ppm)

Alternative	2017		2047	
	1-hour	8- hour	1-hour	8- hour
NAAQS:	35	9	35	9
Rockland County				
Residential and Sidewalk				
No Build	6.3	4.5	6.3	4.5
Short Span	6.0	4.3	5.9	4.3
Long Span	5.8	4.2	5.9	4.3
Bridge Shared-Use Path				
Short Span	7.1	5.1	7.0	5.0
Long Span	6.3	4.4	6.4	4.5
Westchester County				
Residential				
No Build	10.4	5.1	10.7	5.4
Short Span	10.3	5.3	10.6	5.5
Long Span	9.6	5.0	9.8	5.1
Sidewalk				
No Build	10.6	6.1	10.6	6.1
Short Span	10.6	6.0	10.6	6.0
Long Span	10.6	6.1	10.6	6.1
Bridge Shared-Use Path				
Short Span	13.7	6.9	14.2	7.1
Long Span	12.5	6.3	12.9	6.5
Note: 1-hour background is 3.4 ppm; 8-hour background is 2.5 ppm.				

The projected PM concentration contributions from bridge traffic in the No Build and Replacement Bridge Alternatives (excluding background levels) and the increments as compared to the No Build Alternative are presented in **Table 11-6**. The increments are all projected to be lower than the applicable NYSDOT thresholds.

Note that the PM concentrations on the shared-use path cannot be compared with No Build concentrations since there is no similar path on the existing bridge (the existing bridge has no pedestrian or cyclist access). Therefore, rather than comparing concentration increments at this location with the NYSDOT thresholds, the total predicted concentrations, including background levels, can be compared with the NAAQS in order to assess the air quality along the shared-use path. When adding background concentrations (presented in **Table 11-2**), total maximum concentrations are projected to be lower than the corresponding NAAQS, as shown in **Table 11-7**.

**Tappan Zee Hudson River Crossing Project
Environmental Impact Statement**

**Table 11-6
Maximum Predicted PM Concentration Increments ($\mu\text{g}/\text{m}^3$)**

Alternative	2017			2047		
	PM _{2.5}		PM ₁₀	PM _{2.5}		PM ₁₀
	24-hour	Annual	24-hour	24-hour	Annual	24-hour

No Build	2.7	1.0	5.5	2.6	0.9	5.7
Short Span	2.6	1.0	5.4	2.5	0.9	5.6
Long Span	2.7	1.0	5.5	2.6	0.9	5.7
Maximum Increment	0.0	0.0	0.0	0.0	0.0	0.0
Sidewalk						
No Build	3.9	1.3	8.0	3.7	1.2	8.3
Short Span	3.8	1.3	7.9	3.7	1.2	8.2
Long Span	3.9	1.3	8.0	3.7	1.2	8.3
Maximum Increment	0.0	0.0	0.0	0.0	0.0	0.0
Notes:						
The projected increment from No Build to the Replacement Bridge Alternative is compared with the NYSDOT incremental thresholds.						
Background concentrations are not included.						
Negative numbers indicate a projected decrease in maximum concentrations.						

**Table 11-7
Maximum Total Predicted PM Concentrations
Along Shared-Use Path ($\mu\text{g}/\text{m}^3$)**

Alternative	2017			2047		
	PM _{2.5}		PM ₁₀	PM _{2.5}		PM ₁₀
	24-hour	Annual	24-hour	24-hour	Annual	24-hour
<i>NAAQS:</i>	35	15	150	35	15	150
Rockland County						
Short Span	30.4	10.1	72.8	30.4	10.1	74.8
Long Span	29.6	9.9	71.2	30.0	10.0	72.4
Westchester County						
Short Span	31.2	10.6	70.0	31.0	10.5	70.6
Long Span	30.5	10.4	68.7	30.5	10.3	69.2
Notes:						
The total predicted concentrations include the projected increment from bridge traffic added to background levels presented in Table 11-2 .						
These maximum levels are conservatively high for most portions of the bridge since the sections near and over the water will benefit from increased wind speed and ensuing pollutant dispersion due to the height above the water and the microclimate conditions above the Hudson River. Also, for 24-hour concentrations, it is assumed that the peak increments coincide with the highest background levels.						

Overall, no exceedances of the NAAQS or applicable incremental thresholds are projected. Furthermore, a few features of the replacement bridge options would reduce pollutant emissions as compared to the No Build Alternative:

- The Replacement Bridge Alternative would replace the existing lanes (portions of which are approximately 11 feet wide) with 12-foot-wide lanes, improving safety on the bridge. The replacement bridge would also introduce shoulder areas for vehicles involved in accidents and breakdown incidents and for emergency vehicle access, thereby improving the traffic flow and reducing the substantial delays that these incidents cause (the existing bridge experiences a high accident rate, as described in Chapter 1, “Purpose and Need”).
- The introduction of three highway-speed toll lanes (replacing the two existing 35 mph lanes) would reduce congestion and idling emissions at the toll plaza.
- The replacement bridge would have four lanes in each direction, eliminating the need to move the median barriers twice daily (currently accomplished using a specialized diesel engine, taking approximately half an hour for each switch) and improving traffic flow during those times.

11-6 MITIGATION

Since no exceedances of the NAAQS or applicable incremental thresholds were projected to result from the Replacement Bridge Alternative, mitigation is not required.
